December 2021

Abstract

The facial expression that someone shows has consequences for how that person is treated. We study whether people display facial expressions strategically. In two laboratory experiments, participants play task delegation games in which managers assign a task to one of two workers. When assigning the task, managers see pictures of the workers and we vary whether getting the task is desirable or not. We find that workers strategically adapt their facial expressions to the incentives they face, and that it indeed pays off to do so. Yet, workers do not exploit the full potential of the strategic display of facial expressions.

*We thank numerous seminar and conference audiences, and especially Martin Dufwenberg, Uri Gneezy, Alex Imas, Theo Offerman, Giorgia Romagnoli, Sigrid Suetens and Frans van Winden for helpful suggestions and comments. We would like to acknowledge financial support from the ANR project SINT ANR-15-CE33-0005-01 as well as support from the Institute for Advanced Study in Toulouse (IAST) and the LABEX CORTEX (ANR-11-LABX-0042) of Universite de Lyon, within the program Investissements d’Avenir (ANR-11-IDEX-007). A previous draft of this paper circulated under the title “The Strategic Display of Emotions”.

Facial expressions are rapidly perceived and evaluated ([Ambady & Rosenthal, 1992](#); [Ambady et al., 2000](#)). They are used to judge personality, values and dispositions of interaction partners, and the most prominent facial expressions are linked to emotions ([Frijda, 1986](#); [Ekman, 1993](#)). Emotions play an important role in strategic settings ([Battigalli et al., 2015](#); [Loewenstein, 2000](#); [Frank, 1987, 1988](#); [Hirshleifer, 1984](#)).¹ They affect people's choices, and others respond to this. Anger is a good illustration of this. Angry people are willing to destroy surplus ([Bosman & Van Winden, 2002](#)). In response, people that are known to have a predisposition to get angry enjoy a better treatment in bargaining settings. Even in one-shot interactions, in which predispositions are not revealed through reputation, emotions can convey intentions effectively ([Frank, 1988](#)). An accumulating body of empirical evidence supports these ideas. The display of anger during negotiations leads to more favorable offers ([Reed et al., 2014](#); [Andrade & Ho, 2009](#); [van Kleef et al., 2004](#)) and smiling fosters trust ([Scharlemann et al., 2001](#); [Centorrino et al., 2015](#)).

Given the strategic value of expressing emotions, people have clear incentives to mimic those facial expressions. While facial expressions are not fully under a person's control (such as blushing), to some extent they are ([Frijda, 1986](#); [Ekman, 1993](#)). This opens up the possibility that facial expressions are used strategically. Surprisingly, there are virtually no studies that test the strategic use of facial ex-

¹Early accounts of the role of emotions in economics can be found in [Smith \(1759\)](#) and [Bentham \(1789\)](#), see also [Ashraf et al. \(2005\)](#). Our focus is on the role of emotions in social interactions. Emotions are also important in the domain of individual decision making. See for instance the work by [Loomes and Sugden \(1982\)](#) on regret and disappointment, or [Gneezy et al. \(2014\)](#) on the role of guilt in pro-social behavior.

pressions. This is in sharp contrast to other types of communication, which has been intensively studied in economics. Yet it is clearly important for a good understanding of the role of nonverbal communication. It speaks to the question whether it can be equilibrium behavior to pay attention to facial expressions and what the level of people's sophistication is in this respect.

Our main contribution is to study whether people strategically adjust their facial expressions in different economic games. In a laboratory experiment, participants play a task delegation game. In this game, a 'manager' assigns an investment task to one of two 'workers'. The main treatment variation is whether getting the task is desirable or not for the worker (in monetary terms). This crucially changes the strategic nature of the game for workers. In either treatment, the manager benefits from a worker's investment in the task, while investing is always costly to the worker. It is therefore in the manager's interest to assign the task to the worker that is most likely to invest. Many tasks in organizational environments fit this setting. For instance, some tasks are perceived as relatively pleasurable (teaching a course on game theory), while others are best avoided (administrative duties).

Our main interest is in whether the worker's facial expression affects the likelihood of getting the task and whether workers exploit this by adapting their facial expressions. It is worth emphasizing that those facial expressions need not necessarily be related to emotions. However, in one of our experiments we explicitly ask workers to express emotions, and the software we use to read facial expressions also detects different expressed emotions. We hypothesize that workers use different

facial expressions to induce (dis)trust by the manager. We indeed find that facial expressions affect trustworthiness perceptions, but it can equally well be that workers are trying to convey other signals, such as social preferences, or induce reciprocity by the manager. These interpretations are not essential to the questions we want to answer: Do facial expressions matter and do workers adapt their facial expressions? We also emphasize that our study is about *expressing* emotions, and not about actual emotions felt by workers.

In the experiment, workers could take pictures of themselves, and send these to the manager. We hypothesize that the expression of positive emotions on these pictures, like happiness, is associated with higher perceived trustworthiness. Likewise, we expect that negative emotions, and especially anger, are associated with lower perceived trustworthiness. If so, workers can avoid getting the task by showing less positive and more negative emotions. We therefore predict that workers would show more negative emotions when the task is undesirable to get.

We present results from two experiments. In Experiment I, we instructed workers to take one picture on which they looked happy and one picture on which they looked angry. Workers could then choose which picture they wanted to show to the manager. Their choice was implemented probabilistically, such that in some rounds their non-preferred picture was shown. The advantage of this setup is that it gives us a counterfactual, providing us with a clean causal identification of the effect of different facial expressions on the managers' decisions. Managers were not made aware of the fact that workers were instructed to express emotions. We did this so

that the managers would not immediately question the sincerity of specific facial expressions. In Experiment II, workers were not given any instructions on how to look on the pictures. The advantage of this setup is that we can study the extent to which participants adjust their facial expressions spontaneously.

The main findings are that workers adapt their facial expressions to the strategic environment. Workers are more likely to show negative emotions when the task is not desirable than when the task is desirable. Moreover, workers can indeed avoid getting the task by expressing negative emotions (anger). Specifically, managers are less likely to assign the task to workers that express more negative emotions. We hypothesized that managers associate negative emotions with a lower inclination to invest. Consistent with this, workers that express more negative emotions are rated as less trustworthy by an independent panel of subjects. Anticipating this, workers in Experiment I are twice as likely to show anger when the task is undesirable compared to when the task is desirable. In Experiment II, workers expressions are characterized by negative valence when the task is undesirable, as measured by automated facial analysis software. Thus, they spontaneously adapt their facial expressions to fit the situation. However, they only exploit the potential benefits to a limited extent, and the difference in expressions between treatments is only 35 percent of that observed in Experiment I. This finding is especially striking in light of the fact that their only means to influence managers was through the pictures they send.

We also propose a model that can accommodate the findings from our experi-

ments. In the model, we assume that senders ('workers') can send messages about their emotions by varying their facial expressions. Senders have a cost of lying or faking expressions, i.e. expressing an emotion different from what they truly experience. We show that in equilibrium, senders will overreport their emotional valence when the task is desirable and underreport their valence when the task is undesirable. If the cost of faking expressions is sufficiently high, there will be partial separation of types. This implies that senders strategically adapt their messages to the situation they face, while receivers ('managers') respond to the messages they observe.

To our best knowledge, ours is the first paper to study the strategic display of facial expressions, in the sense that people adapt their facial expression to fit the situation.² It fits well in the literature on cheap talk ([Crawford & Sobel, 1982](#); [Farrell & Rabin, 1996](#)), in the sense of sending signals about private information or intentions. In that literature, the focus is on verbal messages. Most closely related is the work by [Andrade and Ho \(2009\)](#), who show that people strategically over-report their level of anger in verbal messages. While verbal and nonverbal messages have many similarities, they are distinct in some key respects. Nonverbal cues can be harder to fake ([Ekman, 1993](#); [Centorrino et al., 2015](#)). Furthermore, when the facial expression of a person does not match the contents of his or her verbal statement, people may rely more on the former. [Reed et al. \(2014\)](#) indeed document a much

²Some of the existing literature uses the term strategic display to mean something different. They use strategic display to signify that emotional displays have strategic value. For instance, [Kopelman, Rosette, and Thompson \(2006\)](#) study if displaying different emotions has effects on outcomes, but they do not test if people make use of this fact.

smaller impact of verbal messages if they are accompanied by a facial expression that does not match the statement. This suggests that nonverbal cues like facial expressions, may be of first-order importance.

Some papers show that people strategically manipulate emotions in others. Specifically, when people have the option to anger their opponent, they do so in environments in which this pays off to do ([Gneezy & Imas, 2014](#)). In contrast, our paper shows that people strategically manipulate their own facial expressions. In a theoretical contribution, [Winter et al. \(2016\)](#) analyze equilibrium play when people can choose their own emotional states.

Our study also relates to a growing literature showing the importance of facial cues more generally. In many economic interactions, people highly value facial cues. For many jobs, face-to-face interviews are a key part of the recruitment procedure,³ and most people post pictures of themselves on their professional websites. Online marketplaces such as Airbnb and Uber make it possible for buyers and sellers to see each other on pictures before trading. Business people spend large amounts of time and money to meet with their business partners before signing a contract ([Forbes, 2009](#)). In trust games, many people are willing to pay to see a picture of the other ([Eckel & Petrie, 2011](#)) or to show their own picture to others ([Heyes & List, 2016](#)). Facial cues are somewhat predictive of behavior. Based on seeing pictures of unknown others, observers can predict behavior in strategic situations slightly

³The recruiting platform *HireVue* analyzes facial expressions as part of the process (see this [CNN article](#)). In an experiment, [Mobius and Rosenblat \(2006\)](#) show that attractiveness has an impact on hiring decisions, and see e.g. [Hamermesh and Biddle \(1994\)](#) for empirical evidence.

above chance levels (Verplaetse et al., 2007; Bonnefon et al., 2013; Vogt et al., 2013; Tognetti et al., 2013; van Leeuwen et al., 2018).

1 Task delegation games and hypotheses

In the experiment we use a novel task delegation game, loosely inspired by the games used in Babcock et al. (2017). In this game, a ‘manager’ is paired with two ‘workers’ (neutral labels are used in the experiment). The manager sees pictures of the workers and has to allocate an investment task to one of them. The chosen worker becomes the ‘designated’ worker and is the only worker that has to make a decision. The designated worker can accept or refuse to invest. Investing is costly to the worker but beneficial to the manager. We implement two versions of the game, that differ only in the payoffs. We vary the payoffs such that in one version it is beneficial to the worker to get the task (treatment ‘Desirable’) while in the other version it is not (treatment ‘Undesirable’).

Figure 1 illustrates the two versions of the game when the manager (M) assigns the task to worker A, and thus worker A becomes the designated worker (the case where the task is assigned to worker B is symmetric). In treatment ‘Desirable’, the designated worker (A) always earns more than the other worker (B), independent of his investment decision. The designated worker earns €2 if he invests, and €2.2 if he refuses to invest. The other worker always earns €1. The manager earns €2 if the designated worker invests, and €1 if the designated worker refuses to invest.

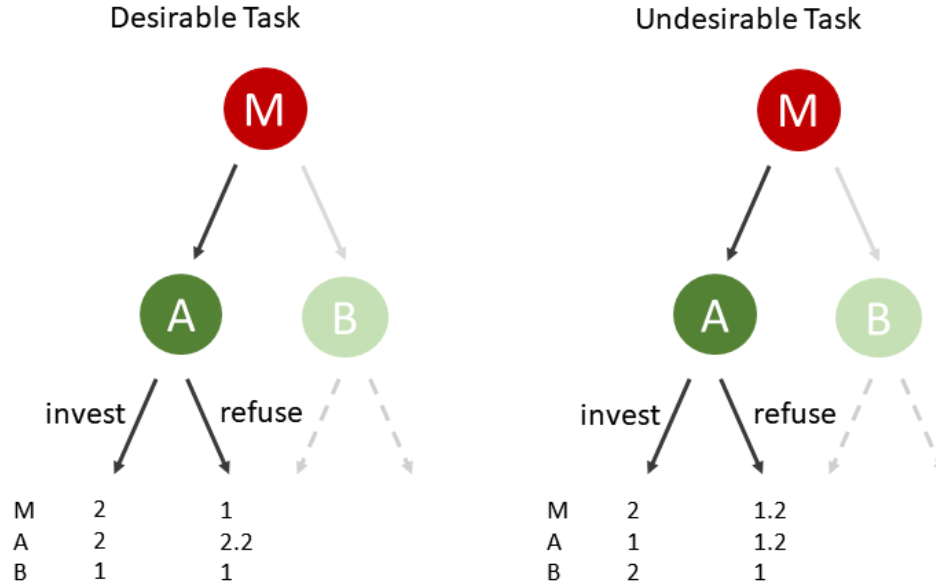

Figure 1: Payoffs to manager (M) and workers (A and B) when the task is assigned to worker A (i.e., worker A is selected to make a decision). The case in which the task is assigned to worker B is symmetric.

In treatment 'Undesirable' (right part of Figure 1), a worker earns most if the task is assigned to the other worker and the other worker invests. In this version, if the designated worker (A) refuses to invest, the other worker (B) has to invest. The worker that ends up investing always earns €1. The worker not investing earns €2 if the designated worker invests and €1.2 if the designated worker refuses.

Note that in both versions of the task delegation game, the manager earns more money if the designated worker invests. This creates incentives to allocate the task to the worker that is most likely to invest, and therefore to select the worker that looks most trustworthy. If so, workers have incentives to appear trustworthy in

Desirable in order to receive the task. In Undesirable, they may wish to appear untrustworthy to avoid getting the task.⁴ We conjecture that negative emotions (such as anger) are associated with lower trustworthiness, and positive emotions (such as happiness) are associated with higher trustworthiness.

Hypothesis 1. *In both treatments, managers are more likely to assign the task to workers that show more positive facial expressions.*

Hypothesis 2. *Workers display more negative facial expressions in treatment Undesirable compared to treatment Desirable.*

We test these hypotheses in two experiments. The two experiments differ in the way how workers can display their facial expressions. The two experiments are complementary. In Experiment I we impose that workers either show a happy or an angry facial expression. While stylized, this allows us to cleanly identify the causal effect of facial expressions. Experiment II is more natural, allowing for more freedom in the way workers can display facial expressions. We will first discuss the design and main results of Experiment I before turning to Experiment II.

⁴There is a caveat. If a worker is very pessimistic about the likelihood that the other worker will invest, he may be better off by getting the task himself and not investing.

2 Experiment I

2.1 Experimental design and procedures

Prior to receiving any instructions about the game, participants in the role of workers were asked to take two pictures of themselves using a webcam. Participants were instructed to look natural on both photos and to display a happy expression on one picture and an angry expression on the other. Participants were allowed to retake pictures until they were satisfied with the result. The same two pictures were used throughout the experiment. All subjects - workers and managers - then received instructions on their screen (see Appendix C). Participants also received a hard-copy with a summary and were asked to respond to a series of control questions before continuing.

Participants played either the desirable or undesirable version of the task delegation game in a between-subject design. Each subject played a total of 12 rounds and was paid for every round. Subjects were rematched every round. Managers never saw the same worker more than once and workers never found out with which other worker they were matched. For each session, we recruited as many managers as workers. This way there were enough managers to ensure that a manager never saw the same worker twice. Since workers were paired, this means half of the managers were inactive in any round. Managers received a fixed payment of €1 in each round in which they were not making a decision.

At the beginning of every two rounds, workers could indicate which picture (the

happy or the angry picture) they want to use for the next two rounds. In these next two rounds, the preferred picture was used in one round, while in the other round it was randomly determined (with equal probability) which picture was shown. This way, we have information about the worker's preferred choice, and at the same time the random variation creates a set of counterfactuals which allows us to establish the causal effect of facial expressions on the likelihood of getting the task. Managers were not informed that workers were asked to express emotions or how pictures were selected and workers knew this. We did this so that the managers would not immediately question the sincerity of the expressed emotions.

At the end of each round, all subjects received feedback about their earnings. If they were not the designated player, they also learned whether or not the other worker invested. Workers also learned which one of their pictures was shown. Earnings were between €12.00 and €23.40 (mean €15.60). Each session lasted around 75 minutes and ended with a survey in which we collected additional information. To preserve anonymity, worker and managers came from different cities in the Netherlands. Workers participated in Amsterdam (CREED lab) and managers in Tilburg (CentERlab). We recruited a total of 272 subjects, 136 in each role (51 percent female, mean age 22) for a total of 10 sessions.⁵ Each session had 24, 28, or 32 participants, depending on the show-up. Sessions were gender-balanced, with a fraction of females that was always between 0.42 and 0.60.

⁵Prior to running this experiment, we conducted one pilot session in which we used different games (a trust game and ultimatum game). We decided to change the design to make the games more comparable and to create a situation in which looking angry has clearer potential benefits.

Workers provided consent for the use of their pictures in the experiment. They were seated in closed, sound-proof cubicles. When taking pictures, participants were told to capture their entire face and to look into the camera. Pictures were taken with a high-quality webcam (Logitech HD 1080p). Ethical approval was granted by the IRB of the Faculty of Economics and Business at the University of Amsterdam.

2.2 Measurements

Intensity of expressed emotions. We use facial recognition software (FaceReader 7.1, [Bijlstra & Dotsch, 2011](#)) to evaluate the intensity of expressed emotions. FaceReader classifies facial expressions based on the relative position of 538 grid-points on the face. It is based on an artificial neural network trained on over 10,000 images. For each emotion it gives a value between 0 and 1, reflecting the intensity of the expressed emotion on that picture. The software could successfully capture the face in all but one picture. Throughout the analysis, we use valence as a composite measure of the intensity of expressed emotions. Valence is defined as the difference between positive and negative emotions, and can vary from -1 (very negative) to +1 (very positive).⁶

Perceived trustworthiness and attractiveness. An independent group of raters evalu-

⁶Valence is calculated as the level of 'happy' minus the maximum level of any negative emotions (anger, sad, scared, and disgust). Subjects in our experiment express very little negative emotions besides anger, so that valence is essentially the level of 'happy' minus the level of 'anger'.

ated pictures on trustworthiness and attractiveness on a 7-point scale. Each picture was evaluated by 8 raters (4 males, 4 females) on each dimension. Raters were recruited from the same subject pool as the managers. A total of 32 raters evaluated one picture of each of the 136 workers (either happy or angry, randomly selected). Each rater evaluated pictures on only one dimension and pictures were sorted by gender. Raters received a flat payment of €7, the rating task lasted around 20 minutes. The interrater reliability is high (Cronbach's alpha: 0.809 and 0.814 for trustworthiness and attractiveness, respectively).

Strategic reasoning, emotional intelligence and sociodemographic data. We collected information on gender, the level of strategic reasoning, and emotional intelligence. The level of strategic reasoning is measured using an adapted version of the race game (Gneezy et al. (2010), and see also Dufwenberg et al. (2010)). This captures a subject's ability to perform backward induction. Emotional intelligence is measured in two ways. The first is performance on the 'Reading the Mind in the Eyes' test (Baron-Cohen et al., 2001), a standard test in psychology where subjects are asked to match one of four emotions to a pair of eyes. The second is the subject's ability to predict who would reject a low offer in an ultimatum game, based on facial expressions (see the task developed in van Leeuwen et al., 2018). We refer to this test as the 'angry button test'. The advantage of this test over the 'eyes test' is that it is more behavioral; subjects predict how people will behave. None of the measures were incentivized. For more details see Appendix A.

Figure 2: Valence and perceived trustworthiness on pictures. Valence is defined as the difference between positive and negative emotions. Bars indicate the mean valence by expression on the picture, circles/diamonds represent individual pictures.

2.3 Results

2.3.1 Facial expressions and perceived trustworthiness

We confirm that facial expressions are different between the happy and angry pictures. The left-hand panel of Figure 2 shows a substantial difference in valence between the two sets of pictures. As expected, mean valence is negative on the angry picture (-0.38) and positive on the happy picture (0.70). All but one subject display higher valence on the happy picture and the difference in valence between pictures is highly significant (signed-rank test, $p < 0.001$, $N = 135$).⁷

We further observe a clear link between expressed emotions and trustworthiness

⁷For all non-parametric tests we report, we take a subject as the independent unit of observation.

ratings. The right-hand panel of Figure 2 shows that perceived trustworthiness is strongly positively associated with valence ($\rho = 0.654, p < 0.001$). A subject fixed-effects regression reveals that an increase of valence by one standard-deviation increases trustworthiness by 0.47 points ($p < 0.001$). Perceived trustworthiness is substantially higher on the happy picture (mean = 4.67) compared to the angry picture (mean = 3.43). Almost all subjects (125 out of 136, or 92 percent) look more trustworthy on their happy picture than on their angry picture, and this difference is highly significant (signed-rank test, $p < 0.001, N = 136$).

2.3.2 Behavior by managers

Our main research question is whether subjects strategically adapt their expression to the situation. This presumes that there is some benefit of choosing a certain expression.

We find clear evidence that the expression matters for the manager's decision. For both task types, managers are more likely to assign the task to a worker that looks happy. When two workers express different emotions, the one that looks happy is 17 percentage points more often chosen when the task is desirable (signed-rank test, $p = 0.019, N = 70$) and 29 percentage points more often when the task is undesirable (signed-rank test, $p < 0.001, N = 65$).

Table 1 shows the estimates of the likelihood that the task is assigned to a worker. The reported coefficients are in terms of odds ratios. In both task types, a happy expression significantly increases the likelihood of becoming the designated worker

Table 1: Assignment of tasks in Experiment I

| Task: | (1) | (2) | (3) | (4) | (5) | (6) |
|---------------------------|---------------------|---------------------|-------------------|--------------------|--------------------|------------------|
| | Undesirable | | | Desirable | | |
| Sample: | All | Same sex | All | All | Same sex | All |
| Happy picture | 1.818*** (0.270) | 2.241*** (0.534) | 1.663 (0.520) | 1.405** (0.207) | 1.548** (0.306) | 1.351 (0.399) |
| Valence | | | 0.853 (0.197) | | | 0.867 (0.194) |
| Perceived trustworthiness | | | 1.248* (0.148) | | | 1.142 (0.139) |
| Observations | 792 | 392 | 792 | 836 | 400 | 816 |
| Wald test (p-value) | < 0.001 | 0.001 | < 0.001 | 0.021 | 0.027 | 0.119 |

Notes: Conditional logit estimates (odds ratios). Dep. var.: being the designated player. Column (6) has fewer observations because FaceReader did not capture every face. Robust s.e. in parentheses clustered at the manager level. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$.

(columns 1 and 4). We find similar effects if we restrict worker-pairs to be of the same sex (columns 2 and 5). This implies that the effect is not driven by gender differences. As both valence and perceived trustworthiness are larger on happy pictures, it is interesting to see which factor is more important for managers, and if the intensity of valence or trustworthiness matters. Columns 3 and 6 show that only perceived trustworthiness is significant in the case of an undesirable task, supporting the idea that managers look for trustworthy-looking workers.

An important design feature is that in half of the cases it was randomly determined whether the happy or the angry picture was shown to the manager. This allows us to cleanly investigate the causal effect of emotional expressions on the likelihood being selected by the manager. To exploit this random variation, we

compute for each worker the fraction of times they received the task when their happy or angry picture was *randomly* shown. We find that subjects in both treatments are on average 13 percentage points more likely to be the designated player if the happy picture is randomly shown (signed-rank tests, $p = 0.024$, $N = 65$ for treatment Undesirable and $p = 0.018$, $N = 67$ for treatment Desirable).

In Appendix B, we show that the estimated effect of showing the happy picture survives several robustness checks. In particular, we find similar effects if we separately consider male-male and female-female pairs. Estimated coefficients are also unaffected by excluding managers that did not correctly answer all comprehension test questions on the first attempt, or restricting observations to photographs on which workers were rated to look ‘natural’ (see Table A.1).

2.3.3 Facial expressions by workers

Our results indicate that there are clear benefits for workers of sending the happy expression when the task is desirable and the angry expression when the task is undesirable. We find that workers act in accordance, and are roughly twice as likely to send their angry picture when the task is undesirable compared to when the task is desirable (44 percent versus 21 percent, left panel of Figure 3), a difference that is highly significant (ranksum test, $p < 0.001$, $N = 136$). The right panel of Figure 3 shows that this difference already exists in the first rounds and persists over the rounds.

Note that workers do not always show the hypothesized ‘optimal’ picture, i.e.,

Figure 3: Fraction of workers choosing the angry picture. Left panel: fraction across all rounds (error bars indicate +/- 1 s.e.). Right panel: fraction over time (per decision made every two rounds).

the picture that yields the highest expected earnings. However, this is not evidence per se that they are making the wrong choice. The picture that maximizes expected earnings might not be the same for all workers. Conceivably, some workers are better off by sending their angry (happy) picture when the task is desirable (undesirable). This, however, is not the case. To show this, we again exploit our design feature that it is sometimes randomly determined which of the worker's pictures is shown, but this time for the subset of cases in which workers sent the 'wrong' picture. For this subsample, we find again that sending a happy picture increases the likelihood of being the designated player. For cases in which workers want to show the 'wrong' picture, the happy picture increases the likelihood of being selected by 22 percentage points with the undesirable task (signed-rank test, $p = 0.009$, $N = 44$)

and by 28 percentage points with the desirable task (signed-rank test, $p = 0.090$, $N = 16$).

2.3.4 Investment by workers

For completeness, we briefly report investment behavior by workers. Overall, in 35 percent of the cases workers invested when they were assigned the task. This investment rate is somewhat lower when the task is undesirable (28 percent versus 41 percent) but the difference is not significant (ranksum test, $p = 0.254$, $N = 136$).

Are managers right to select the workers that look happy? We find a modest link between the expression on the picture and the worker's investment choice.⁸ We note, however, that our experimental design is not well suited to answer this question. The sample of workers making an investment decision is a selective sample, chosen by managers. We therefore cannot establish any causal link between expressed emotions and investment behavior. This would require knowledge about the counterfactual, i.e., what the investment decision of the other worker would have been.

3 Experiment II

Subjects in Experiment I understand the strategic benefits of adapting their facial expressions to the situation. Possibly, the request to express different emotions on

⁸In the Desirable task treatment, workers who prefer to show their happy picture invested in 45 percent of the cases. This is 27 percent for those who prefer to show their angry picture. In the Undesirable task treatment we find no difference (30 vs 27 percent investment).

the pictures made them aware of the potential benefits. In Experiment II, we study whether subjects spontaneously adapt their facial expressions.

The setup of Experiment II is very similar to Experiment I. The main difference is that this time we did not instruct them to express emotions on the pictures. Instead, in Experiment 2 subjects in the role of workers took a new picture at the start of each round. Emotions or facial expressions were never mentioned in the instructions. We predicted that the expressed emotions would be less extreme in this setup, making it harder to detect any differences. We therefore used a within-subject design to increase statistical power. Each subject played six rounds in each version of the game, and we varied the order of the games across sessions. Participants only received the instructions for the second part after completing the first part.⁹

We conducted 5 sessions, again with managers in Tilburg (CentERlab) and workers in Amsterdam (CREED lab). In total, 148 subjects participated in Experiment II, with 74 subjects in each role (54 percent female, mean age 22). Sessions lasted about 75 minutes, and subjects earned between €13.40 and €23.60 (mean €17.40).

3.1 Measurements

Emotional expressions. Emotional expressions were again evaluated using FaceReader.

FaceReader could successfully read emotions on 866 out of 888 pictures (97.5 per-

⁹The instructions for Experiment II can be found in Appendix C. In the first session of Experiment II, some subjects used hand gestures on the pictures and some considerably slowed down the experiment by taking many selfies before submitting their picture. We therefore slightly modified the instructions in that treatment, and told participants that they were not allowed to use hand gestures, and limited the number of possible selfies to three. An experimenter inspected the submitted pictures. Subjects rarely violated the instructions. If they did, they were asked to retake the picture.

cent).

Perceived trustworthiness. We followed similar procedures to obtain ratings of perceived trustworthiness. We recruited 24 raters (12 males, 12 females) at the Centerlab in Tilburg, who each rated one picture of each of the 74 workers. Half of the pictures that a rater saw came from treatment Desirable, and the other half from treatment Undesirable. Hence, each picture was rated twice, and each worker was judged by 24 raters.

Strategic reasoning, emotional intelligence and sociodemographic data. We used the same final survey collecting information on gender, the level of strategic reasoning, and emotional intelligence, as in Experiment I.

3.2 Results

3.2.1 Facial expressions by workers

We again find evidence that subjects strategically express emotions. The mean valence when the task is desirable is 0.24, against a mean valence of 0.15 when the task is undesirable, a difference that is statistically highly significant (signed-rank test, $p < 0.001$, $N = 74$). The majority of subjects (73 percent) displays a higher valence in the desirable task. We also find that workers appear more trustworthy when the task is desirable. The average trustworthiness rating is 0.20 points higher in treat-

ment Desirable (signed-rank test, $p = 0.012$, $N = 74$), and the majority of raters (83 percent) gives a higher average rating in treatment Desirable. In qualitative terms, this is consistent with the results from the previous experiment.¹⁰

In terms of magnitude, the difference between tasks is much more modest. The top panel of Figure 4 shows the mean valence on the happy and angry pictures (squares, top line) from Experiment I. The difference of 1.08 gives an indication of what subjects can maximally achieve in terms of expressing different emotions. Workers do not achieve this maximal difference, because subjects do not always send the happy picture when the task is desirable or the angry picture when the task is undesirable. The observed difference in valence is 0.26 in Experiment I (dots, top line). This is about three times as high in Experiment II, where the difference in valence is 0.09 (dots, bottom line). Thus, the difference in valence across treatments in Experiment II is only 35 percent of the difference observed in Experiment I. Similarly, the bottom panel of Figure 4 shows the differences in perceived trustworthiness in both experiments. The difference in perceived trustworthiness between treatments is again smaller in Experiment 2 than in Experiment 1. The treatment difference in perceived trustworthiness in Experiment 2 is only 63 percent of the difference in Experiment 1.

Kernel estimates of the distribution of valence on the pictures selected by sub-

¹⁰An alternative explanation would be that subjects display higher valence with the desirable task because they ‘enjoy’ this task more, for example because payoffs are somewhat higher with this task. The data is not consistent with such an explanation. In Table A.2 in Appendix B, we show fixed effects regressions estimating the relation between valence and payoffs in the previous round. We find no significant effect of payoffs on valence with either task.

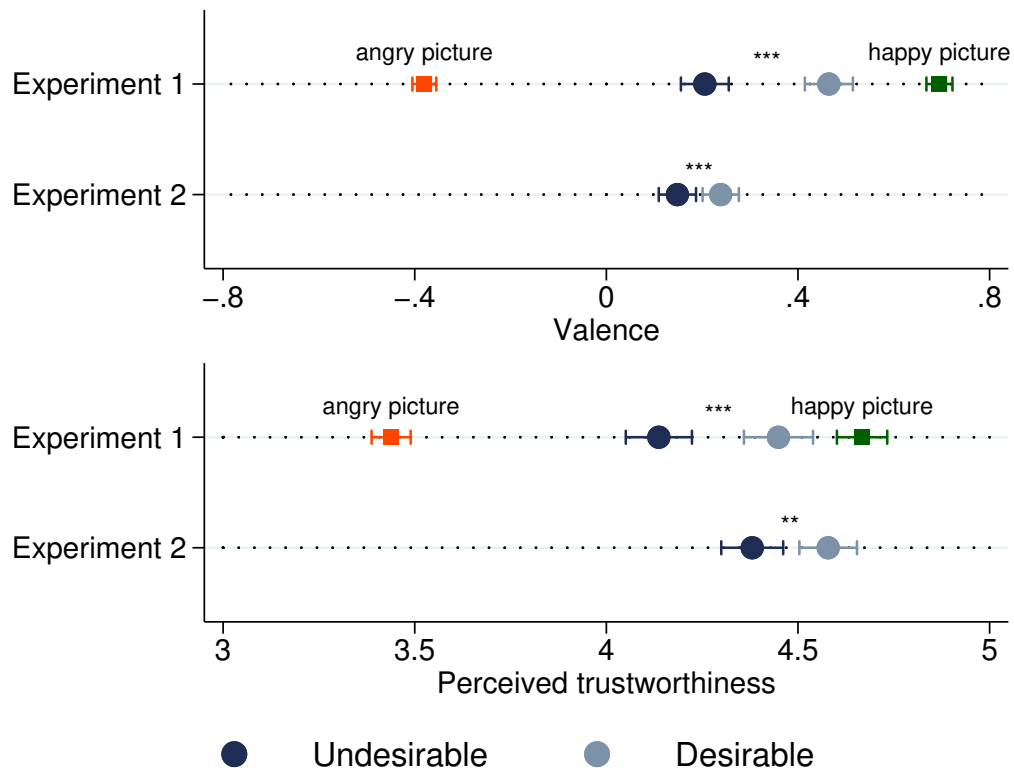

Figure 4: Mean valence and perceived trustworthiness on pictures taken and pictures sent. Squares indicate the mean valence (top panel) and perceived trustworthiness (bottom panel) on happy and angry pictures taken. Dots indicate the mean valence (top panel) and perceived trustworthiness (bottom panel) on pictures sent. Error bars indicate +/- 1 s.e. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$, relate to treatment differences.

Figure 5: Kernel estimates of the distribution of valence on send pictures.

jects provide additional support (see Figure 5). In both experiments we see a shift in the distributions across the different tasks, illustrating that subjects do respond to the strategic situation they face. In Experiment I, valence has substantial mass almost everywhere on the scale. By contrast, in Experiment II it is much less dispersed and largely concentrated around 0, with little mass below zero.

3.2.2 Behavior of managers

While subjects in Experiment II vary their expressions to a lesser extent, the potential benefits appear to be of a similar magnitude. Table 2 shows the effect of valence on the likelihood of becoming the designated player. The odds ratios are above one for both tasks and both experiments. The coefficient is not significant for the undesirable task in Experiment II (column 2). This is probably due to a

Table 2: Assignment of tasks: Experiments I and II

| Task Sample | (1) | (2) | (3) | (4) |
|----------------|---------------------|------------------|-------------------|--------------------|
| | Undesirable | | Desirable | |
| | Experiment I | Experiment II | Experiment I | Experiment II |
| Valence | 1.447*** (0.164) | 1.360 (0.341) | 1.231* (0.148) | 1.898** (0.531) |
| Observations | 792 | 432 | 816 | 412 |

Notes: Conditional logit estimates (odds ratios). Dep. var.: being the designated player. Robust s.e.in parentheses clustered at the manager level. *** $p < 0.01$, ** $p < 0.05$,* $p < 0.1$.

lack of power; few subjects express strong emotions in that treatment, and especially negative emotions are mostly absent. The odds ratio is, however, in the same ballpark as that in Experiment I (column 1). We also find a very similar correlation between valence and perceived trustworthiness: an increase of valence by one standard-deviation increases trustworthiness by 0.49 points ($p < 0.001$) in Experiment II, and this was 0.47 in Experiment I. We conclude that subjects spontaneously adapt their expressed emotions to the situation, but they only exploit the benefits to a modest extent.

4 Heterogeneity in the strategic display of facial expressions

We next examine if there is heterogeneity in how strategic people are in their facial expressions. We collected information on gender, the level of strategic reasoning,

and emotional intelligence, as described in subsection 2.2.

Our outcome variable concerns the level of strategic use of facial expressions. We evaluate this by the degree to which participants adjusted their expressions to the strategic context. For Experiment 1, we measure how strategic subjects are by the fraction of times that they send the picture that matches the situation; the happy picture when the task is desirable and the angry picture when the task is undesirable. For Experiment 2, we measure how strategic subjects are by the difference in displayed valence between treatment Desirable and treatment Undesirable.

Table 3 summarizes the results. In Experiment I, subjects who score high on the eyes test and angry button test are more strategic, while we do not find a significant impact of the level of strategic reasoning. In Experiment II, we find that people who score better on the angry button test adapt their valence more strongly to the strategic setting. Finally, only for Experiment I we observe a marginally significant gender difference.

5 A model of expression of emotions

In our experiments, subjects in the role of workers adapt their expressed emotions strategically, though only partially, and those in the role of managers pay attention to the expressed emotions. In this section, we present a model that is consistent with this type of behavior. As in the experiment, the expressed emotions are not necessarily felt by workers, but merely used as a signal of intentions.

Table 3: Strategic display of emotions and individual characteristics

| | (1) | (2) |
|--|---------------------|---------------------|
| Sample | Experiment 1 | Experiment 2 |
| Dep. var. | Matching picture | Increase in valence |
| Strategic reasoning score ^a | 0.044 (0.027) | 0.039 (0.030) |
| Eyes test score ^a | 0.105*** (0.031) | -0.027 (0.021) |
| Angry button test score ^a | 0.076*** (0.028) | 0.049** (0.024) |
| Female | -0.094* (0.056) | -0.036 (0.054) |
| Constant | 0.658*** (0.035) | 0.102** (0.044) |
| Observations | 136 | 74 |
| R ² | 0.173 | 0.084 |

Notes: OLS estimates. Column 1: Matching picture is the happy (angry) expression when the task is desirable (undesirable). Column 2: Increase in valence is mean valence when the task is desirable minus mean valence when the task is undesirable. ^a: standardized scores. See Appendix A for a description of the measures. Robust s.e. in parentheses. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$.

We model the situation as a sender-receiver game with multiple senders. Each sender chooses an emotional expression (a 'message') to signal his inclination to invest (his 'type') to the receiver. The receiver then chooses which sender gets the task. The setup closely follows [Kartik \(2009\)](#), who studies a cost of lying in a cheap talk environment, thereby transforming the setting into a costly signalling game. We depart from his setup in three main ways. First, we introduce sender competition. Second, we add a comparative static, reflecting that the task can be desirable or undesirable. The case for an undesirable task resembles the "Lure treatment"

in [Charness et al. \(2018\)](#). Third, the payoff structure differs in different respects. In our setup the receiver always prefers the sender to invest, rather than having an interior optimum. Furthermore, our game falls in the class of 'monotonic signaling games', as in [Cho and Sobel \(1990\)](#).¹¹

There are two senders, $i = 1, 2$. Each sender has a type $t \in T = [0, 1]$. Types are independently drawn from a uniform distribution. The type reflects a sender's probability of investing when that sender is selected by the receiver. For simplicity, we assume that the probability of investing is fixed. The uncertainty may reflect that the sender's willingness to invest depends on idiosyncratic factors, such as his liking for a particular manager or co-worker.

After privately observing his type, each sender sends a message $m \in M = [0, 1]$.¹² In the experiment, the message is the expressed level of valence. The set M is taken to be the set of feasible expressions in terms of valence levels that subjects can achieve. We assume a natural language interpretation, where message m is interpreted by the receiver as 'I am of type m .' After observing both messages, the receiver takes action $a_i \in A = \{0, 1\}$, where $a_i = 1$ means that the task is allocated to sender i and $a_i \neq a_j$ for $j \neq i$.

To keep things tractable, we assume specific functional forms for the payoff func-

¹¹Loosely speaking, in a monotonic signaling game all types of senders rank the actions (including mixed strategies) by the receiver in the same way.

¹²Note that our message space is less rich than in [Kartik \(2009\)](#).

tions of senders and receivers. The payoff function of sender i is given by:

$$U_i^S(a_i, t, m) = \theta a_i - k(m - t)^2, \quad (1)$$

where θ reflects the value of getting the task (including the investment cost), which can be either positive ($\theta > 0$, reflecting the setting in which a task is desirable) or negative ($\theta < 0$, reflecting the setting in which a task is undesirable). The second part of the expression measures the cost of lying or faking emotions, i.e., showing an intensity level of valence that does not match the actual type, where we assume that the actual (experienced) valence of a sender matches his type, and $k > 0$ is a parameter measuring the sender's aversion to lying.

The receiver's payoff function is given by:

$$U^R(a_i, t) = a_i t_i + (1 - a_i) t_j. \quad (2)$$

The receiver should thus select the sender with the highest type (in expectation).

Note that her payoffs are not directly affected by the senders' messages.

In what follows we focus on Perfect Bayesian Equilibria (PBE) in which senders use pure strategies. Pure strategies of senders are functions from type to message. Let $\rho : T \rightarrow M$ be the map of a sender's type to the message sent. Strategies of the receiver are functions from the senders' messages to probabilities over actions $r(m_i, m_j) \in \Delta(\{0, 1\})$. We assume that $r(m, m) = \frac{1}{2}$. $\mu(m_i)$ will denote the receiver's

belief that sender i invests upon receiving message m_i . We further restrict the receiver's off-equilibrium path-beliefs to satisfy D1 (see [Cho and Sobel \(1990\)](#) or [Fudenberg and Tirole \(1991\)](#) for a definition).

We first establish that in any equilibrium the function $\rho(\cdot)$ must be monotonic and nondecreasing. All proofs are in [Appendix D](#).

Lemma 1. *In any PBE, $\rho(t_2) \geq \rho(t_1)$ for any $t_2 > t_1$.*

That $\rho(\cdot)$ must be nondecreasing is intuitive: the benefits of getting the task do not depend on the type, and sending a higher message is less costly for higher types.

Despite the differences in setup, the equilibrium characterization closely matches that in [Kartik \(2009\)](#). It is easy to see that pooling equilibria exist for sufficiently small k , with all types sending the same message. In particular, such pooling equilibria exist if $\theta > 0$ and $2k < \theta$ (with all types pooling at $m = 1$) or $\theta < 0$ and $2k < -\theta$ (with all types pooling at $m = 0$). More interesting for our purposes are (partially) separating equilibria. On any open interval of types that separate, the map $\rho(\cdot)$ must satisfy:

$$\rho'(t) = \frac{\theta}{2k[\rho(t) - t]}. \quad (3)$$

When types on an interval separate, the receiver can deduce the sender's type from the message. This implies that the probability of being selected for sender i is given by $\text{prob}(t_j < t_i) = t_i$. Pretending to be a slightly higher type than their true type increases the payoffs from getting the task at a rate θ , while it increases the cost of lying by $2k(\rho(t) - t)\rho'(t)$ (evaluated at t). It is easy to verify that that in equilibrium

Figure 6: Equilibrium strategies for the case of a desirable task (left, $\theta > 0$) and an undesirable task (right, $\theta < 0$). The figure illustrates a partially separating strategy.

for $\theta > 0$ (desirable task) this implies that $\rho^* > t$ and for $\theta < 0$ (undesirable task) that $\rho^* < t$. Compared to their actual valence, senders express a higher valence when the task is desirable and a lower valence when the task is undesirable. [Charness et al. \(2018\)](#) derive a similar result in a somewhat different tournament setting with two possible types of senders.

Proposition 1. *In any PBE satisfying D1, if $\rho^*(t)$ is part of an equilibrium profile, then (i) if $\theta > 0$, all types $t \in (0, 1)$ overreport their valence, i.e., have $\rho^*(t) > t$, and (ii) if $\theta < 0$, all types $t \in (0, 1)$ underreport their valence, i.e., have $\rho^*(t) < t$.*

With our assumptions on M , it is not possible that all types separate, and therefore some pooling will occur at the top (desirable task) or the bottom (undesirable task). Figure 6 shows a partially separating equilibrium in which there is a single pool (in Appendix D we show that there are no equilibria with multiple pools).

The analysis shows two basic facts. First, senders have an incentive to strate-

gically ‘overreport’ their valence when the task is desirable and ‘underreport’ their valence when the task is undesirable. Second, there can be partial separation, so that receivers should pay attention to the expressed valence. With a slight modification, the model can also accommodate different investment rates across treatments. If senders’ types are endogenous, and reflect senders’ *intentions* to invest rather than necessarily reflecting actual investment decisions, then senders using strategy ρ^* are more inclined to invest when $\theta > 0$ compared to when $\theta < 0$. After overreporting their valence, investing will reduce lying costs. Of course, this assumes that senders are naive and do not anticipate their actual investment decision, otherwise ρ^* is no longer an equilibrium strategy.

6 Discussion and concluding remarks

In this paper we report evidence that people display facial expressions strategically and that it pays off to do so. In two experiments, managers are more likely to assign tasks to workers who express more positive emotions on a picture. Most importantly, in both experiments we find that the desirability of the task influences the workers’ expressions. This result is observed in an environment where workers could choose between an angry and a happy picture (Experiment I), and in an environment where workers send photographs without any mentioning of emotions or facial expressions (Experiment II).

Interestingly, both experiments show evidence that people might not fully ex-

exploit the potential benefits of expressing emotions. In Experiment I, some workers would have been better off (in monetary terms) by sending a different picture. In Experiment II, the difference in intensity of expressed emotions between the Desirable and Undesirable task treatment is only 35 percent of the difference observed in Experiment I. This is especially striking in light of the fact they could only communicate through pictures.

What can explain the reluctance to display certain facial expressions? One possibility is that expressing an insincere emotion comes at a cost. Just as talk may not be cheap, looks may not be cheap. These costs could come from lying or guilt aversion (Ellingsen & Johannesson, 2004; Gneezy, 2005; Charness & Dufwenberg, 2006) or simply a desire to look attractive. It could also be that people do not merely express different emotions, but actually feel them.¹³ Faking emotions might also be cognitively demanding and thus not easy to achieve.

Given that workers strategically manipulate expressions, another question is why managers would respond to expressions. The work by Gneezy and Imas (2014) shows that people *are* aware of the role of emotions of others at some level. Possibly, this level of awareness is only of the first order and not of higher orders (“level-1” reasoning in the parlour of level- k reasoning, Stahl and Wilson (1995); Nagel (1995)). On the other hand, if workers experience costs of manipulating expressions, expressions may contain some informational value. This is similar to a cheap

¹³Meshulam et al. (2012) incentivize recipients in a dictator game to feel angry upon receiving low offers, and find increased physiological arousal among those recipients.

talk framework with lying costs, in which messages transmit information, like the model we propose in section 5. Indeed, previous work shows that facial cues can be informative of behavior. For instance, ‘honest’ smiles are associated with trustworthiness (Centorrino et al., 2015), and pupil dilation is related to deceptive behavior (Wang et al., 2010). There may also be costs on the side of the manager, for instance in scrutinizing whether an expressed emotion is sincere or not. In the presence of such costs or constraints, either on the side of the worker or the manager, facial expressions of emotions could well be informative .

Our results demonstrate that facial expressions might be an important mode of communication. Subjects in our experiments use this form of communication. One interesting avenue for future research is to study how repeated interactions would affect our results. In such a setting, appearing angry might have short run benefits (you avoid receiving an undesirable task), but might have long run consequences as people might avoid future interactions with angry looking people (Elster, 1998).

Appendix A Survey Measures

Level of Strategic Reasoning. The level of strategic reasoning is measured using an adapted version of the race game (see [Gneezy et al. \(2010\)](#)). In our version of the game, a number of chips is available. The subject and computer take turns, and can take 1 or more chips each turn. The player who takes the last chip wins. We implemented two versions. In the first game, they started with 15 chips and they could take 1,2, or 3 chips each turn. In the second game, they started with 17 chips and they could take 1,2,3, or 4 chips each turn. The subject always started first. We programmed the computer such that in every round, there was a winning strategy for the subject if she took the appropriate number of chips from that round onward. A subject's score is the number of rounds that she followed a winning strategy. Once the number of chips remaining is less than the maximum number of chips that a subject can take, the solution is trivial and those rounds are not scored. The mean score is 0.497 (median 0.5, standard deviation 0.183). The instructions can be found in Appendix [C.3.1](#).

Level of Emotional Intelligence. We have two measures of emotional intelligence. The first is based on the 'Reading the Mind in the Eyes Test' ([Baron-Cohen et al., 2001](#)). This is a standard test in psychology, where pictures of eyes are shown together with a set of words describing emotions. The subject's task is to select the word that best fits the expression on the picture. There are 36 pictures in total and

the average score is 25.7 (median 26, standard deviation 4.3). The instructions can be found in Appendix [C.3.3](#).

Our second measure is based on [van Leeuwen et al. \(2018\)](#). We showed ten pictures of participants from a previous experiment who all received a low offer in an ultimatum game. Exactly five of those participants rejected the offer. We asked our subjects to predict which of the participants rejected the low offer. A subject's score is computed as the number of correctly identified rejecters and can range from 0 to 5. The average score is 3.0 (median 3.0, standard deviation 0.9). The instructions can be found in Appendix [C.3.2](#).

Appendix B Robustness

This section provides some robustness checks.

Table [A.1](#) replicates the estimates in columns (1) and (4) of Table 1, showing that our results are robust across different subsamples. Column (1) is an exact replication of the entire sample. Column (2) reports the estimates for worker pairs of the same gender. Columns (3) and (4) split those results by gender. Column (5) shows the results for managers that correctly answered all test questions on their first attempt. Column (6) excludes pairs of workers where at least one of the workers displays deviant behavior. Whether or not a worker displayed deviant behavior is determined by our own coding. Three of the researchers independently rated pictures on deviant expressions. An expression is considered deviant if a participant used props or hand gestures, took abnormal expressions such as kissing or eye-crossing, or exaggerated the emotional expression making it look unnatural. A subject is classified as deviant if at least one of the researchers rated their expression as deviant. The researchers' codings showed strong agreement; about 98 percent of pictures are classified the same by all three researchers.

Table A.1: Assignment of task (Experiment I).

| Sample | (1) | (2) | (3) | (4) | (5) | (6) |
|---------------------------|---------------------|---------------------|--------------------|---------------------|---------------------|---------------------|
| | All | Same-gender | | | Understood | Compliant |
| | | All | Males | Females | | |
| PANEL A: UNDESIRABLE TASK | | | | | | |
| Happy expression | 1.818*** (0.270) | 2.241*** (0.534) | 2.231** (0.726) | 2.250*** (0.681) | 2.476*** (0.605) | 2.000*** (0.316) |
| Observations | 792 | 392 | 172 | 220 | 348 | 722 |
| PANEL B: DESIRABLE TASK | | | | | | |
| Happy expression | 1.405** (0.207) | 1.548** (0.306) | 1.423 (0.339) | 1.750* (0.563) | 1.507** (0.244) | 1.410** (0.212) |

Appendix C Instructions

C.1 Experiment I

C.1.1 Instructions for red players (managers)

General information [identical for both treatments]

Thank you for participating in this study. Please read the instructions carefully and make sure that your mobile phone is turned off. You can earn more money depending on your own choices and the choices of other participants.

In this experiment, there are two types of players: red and green. The green players are all students from another town (Amsterdam). The red players are students from Tilburg. You are one of the red players.

Investment decision [desirable task treatment]

In every round, you are paired with two green players (green A and green B). Exactly one of the green players can make an investment.

Your task is to assign the investment task to one of the green players. That green player becomes the "designated" player. The designated green player can accept or refuse to invest. The other green player has no decision to make.

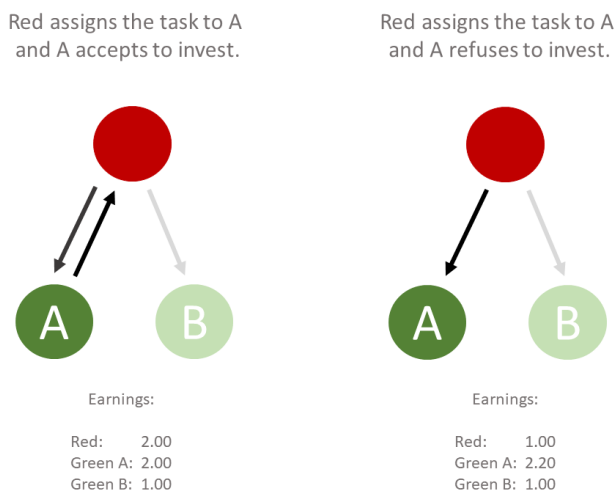

The earnings are as follows:

You earn €2.00 if the designated green player accepts to invest, and €1.00 if the

designated green player refuses to invest. The designated green player earns €2.00 if he or she accepts to invest, and €2.20 if he or she refuses to invest. The other green player always earns €1.00.

Suppose, for instance, that you assign the investment task to green A. If green A accepts to invest, green A and you earn €2.00 each, and green B earns €1.00. If green A refuses to invest, green A earns €2.20, and green B and you earn €1.00 each.

The picture below summarizes the possible earnings when you assign the investment task to green A. Of course, this is just an example; you could also assign the investment task to green B, and the earnings of A and B are then reversed.

Investment decision [undesirable task treatment]

In every round, you are paired with two green players (green A and green B). Exactly one of the green players has to make an investment.

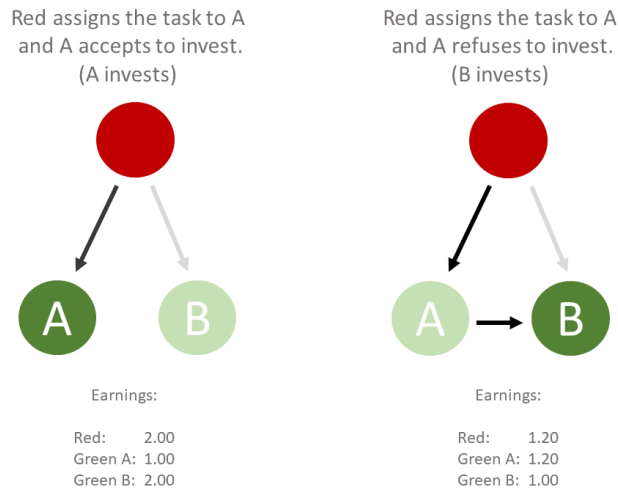

Your task is to assign the investment task to one of the green players. That green player becomes the "designated" player. The designated green player can accept or refuse to invest. If the designated green player refuses, the other green player has to invest.

The earnings are as follows:

The green player that ends up making the investment always earns €1.00. The other green player and you earn €2.00 each if the designated green player accepts to invest, and €1.20 if the designated green player refuses to invest.

Suppose, for instance, that you assign the investment task to green A. If green A accepts to invest, he or she earns €1.00, and you and green B earn €2.00 each. If green A refuses to invest, then green B has to invest. Green A and you earn €1.20 each, and green B earns €1.00.

The picture below summarizes the possible earnings when you assign the investment task to green A. Of course, this is just an example; you could also assign the investment task to green B, and the earnings of A and B are then reversed.

Pictures and rounds [identical for both treatments]

In total, there will be 12 rounds. You will be paid for every round.

When you assign the task to invest, you will see pictures of the green players.

In every round, you will learn whether the green player you assigned the task to accepted or refused to invest.

In half of the rounds, you will be inactive and do not have to make a decision. You will receive €1.00 for each round that you are inactive.

You will be paired with different players in each round. You will never be matched twice with the same green player throughout the entire experiment.

Summary [desirable task treatment]

If you are active in a round, you will see the pictures of the green players you are paired with.

You assign the task to invest to one of the green players.

The designated green player can invest or refuse to invest. The other green player has no decision to make.

You earn €2.00 if the designated green player accepts to invest, and €1.00 if the designated green player refuses to invest. The designated green player earns €2.00 if he or she accepts to invest, and €2.20 if he or she refuses to invest. The other green player always earns €1.00.

There will be 12 rounds, you will be paid for all rounds.

You will be paired with different players in each round. You will never be matched twice with the same green player throughout the entire experiment.

In half of the rounds you will be inactive. If you are inactive you will receive €1.00

Summary [undesirable task treatment]

If you are active in a round, you will see the pictures of the green players you are paired with.

You assign the task to invest to one of the green players.

The designated green player can invest or refuse to invest. When the designated green player refuses, the other green player has to invest.

The (green) player that invests earns €1.00. The other (red and green) players earn €2.00 each if the designated player accepted to invest, and €1.20 each if the designated player refused to invest.

There will be 12 rounds, you will be paid for all rounds.

You will be paired with different players in each round. You will never be matched twice with the same green player throughout the entire experiment.

In half of the rounds you will be inactive. If you are inactive you will receive €1.00

Quiz questions [identical for both treatments]

Please answer the following quiz questions. If you have any questions please raise your hand.

In each of the 12 rounds, you will be matched:

- with the same players
- with different players

Suppose the green player you assigned the task to refuses to invest. How much will you, the designated green player, and the other green player earn?

- You would earn: _____euro
- The designated green player would earn: _____ euro
- The other green player would earn: _____ euro

Suppose the green player you assigned the task to invests. How much will you, the designated green player, and the other green player earn?

- You would earn: _____euro
- The designated green player would earn: _____ euro
- The other green player would earn: _____ euro

C.1.2 Instructions for green players (workers)

Welcome [identical for both treatments]

Thank you for participating in this study. Please read the instructions carefully and make sure that your mobile phone is turned off. You can earn more money depending on your own choices and the choices of other participants.

In this experiment, you will be asked to take pictures of yourself. This is what we will do with your pictures:

- The pictures will be shown to other participants, but only to participants located elsewhere. Your pictures will not be shown to participants at the University of Amsterdam.
- The pictures will be analyzed with facial processing software.

You can choose not to participate in the study. You may withdraw at any time during the study. If you withdraw, no more information will be collected from you and the investigator will ask if the materials already collected in the study can be used.

Results of this study may be used for teaching, research, publications, or presentations at scientific meetings. Your identity or picture will never be disclosed in any of these activities.

By continuing with the experiment you give consent to take part in this study.

- I have read and understood the information above and I want to continue with the experiment.
- I do not want to participate in the experiment.

Taking pictures [identical for both treatments]

In the next steps, you will take some pictures of yourself. To ensure that the pictures are useable, please pay attention to the following factors:

1. Look straight into the camera,
2. Capture your entire face on the picture,
3. Do not wear glasses or other items that cover your face.
4. If you have long hair, please hold them back with an elastic band so that they do not fall into your face.

We will ask you to express different emotions. When you express a certain emotion, try to do this as natural as possible. Try to express the emotion in a convincing way, without overdoing it.

Take a picture [identical for both treatments]

On the next picture we ask you to look angry

Try to look angry [identical for both treatments]

When you take a picture, there will be a 3-seconds countdown.

Picture result [identical for both treatments]

Below is the picture that you took. Please indicate whether you are satisfied with it or want to retake the picture

Take a picture [identical for both treatments]

On the next picture we ask you to look happy

Try to look happy [identical for both treatments]

When you take a picture, there will be a 3-seconds countdown.

General information [identical for both treatments]

In this experiment, there are two types of players: red and green. The red players are all students from another town (Tilburg). The green players are students from Amsterdam. You are one of the green players.

Investment decision [desirable task treatment]

In every round, each red player is paired with two green players (green A and green B). Exactly one of the green players can make an investment.

The task of the red player is to assign the investment task to one of the green players. That green player becomes the "designated" player. The designated green player can accept or refuse to invest. The other green player has no decision to make.

The earnings are as follows:

The designated green player earns €2.00 if he or she accepts to invest, and €2.20 if he or she refuses to invest. The red player earns €2.00 if the designated green player accepts to invest, and €1.00 if the designated green player refuses to invest. The other green player always earns €1.00.

Suppose, for instance, that the red player assigns the investment task to green A. If green A accepts to invest, green A and the red player earn €2.00 each, and green B earns €1.00. If green A refuses to invest, green A earns €2.20, and green B and the red player earn €1.00 each.

The picture below summarizes the possible earnings when the red player assigns the investment task to green A. Of course, this is just an example; the red player could also assign the investment task to green B, and the earnings of A and B are then reversed.

Red assigns the task to A and A accepts to invest.

Earnings:

Red: 2.00
Green A: 2.00
Green B: 1.00

Red assigns the task to A and A refuses to invest.

Earnings:

Red: 1.00
Green A: 2.20
Green B: 1.00

Investment decision [undesirable task treatment]

In every round, each red player is paired with two green players (green A and green B). Exactly one of the green players has to make an investment.

The task of the red player is to assign the investment opportunity to one of the green players. That green player becomes the "designated" player. The designated green player can accept or refuse to invest. If the designated green player refuses, the other green player has to invest.

The earnings are as follows:

The green player that ends up making the investment always earns €1.00. The other green player and the red player earn €2.00 each if the designated green player accepts to invest, and €1.20 if the designated green player refuses to invest.

Suppose, for instance, that the red player assigns the investment task to green A. If green A accepts to invest, he or she earns €1.00, and the red player and green B

earn €2.00 each. If green A refuses to invest, then green B has to invest. Green A and the red player earn €1.20 each, and green B earns €1.00.

The picture below summarizes the possible earnings when the red player assigns the investment task to green A. Of course, this is just an example; the red player could also assign the investment task to green B, and the earnings of A and B are then reversed.

Pictures [identical for both treatments]

The red player will see a picture of you and the other green player when he or she assigns the investment task to one of you. The red player will either see your picture with the happy expression or the picture with the angry expression, and this partly depends on you.

In each round, one of the green players can choose which picture of him- or herself to show. For the other player, this is randomly determined (each picture is equally likely to be selected).

In total, there will be 12 rounds. Every two rounds, you first select which picture you want to show to the red players in the next two rounds. In these two rounds, in random order, your selected picture will be used in one round and a randomly selected picture will be used in the other round.

Feedback [identical for both treatments]

In total, there will be 12 rounds. You will be paid for every round.

At the end of every round, you will learn which of your pictures the red player saw, and whether the red player assigned the investment task to you or to the other green player. If the other green player was chosen, you will also learn whether that player accepted or refused to invest.

Please also note the following:

The red player is not told that one of the green players could choose which picture to show. The red player simply sees the two pictures and then has to assign the task to invest to one of the green players. The red player is also not told that you were asked to express emotions on any of the pictures.

You and the other green player will never see each other's pictures, and you will never find out with whom you were paired in any round. You will be paired with different players in each round. You will never be matched twice with the same red player throughout the entire experiment.

Summary [desirable task treatment]

One of the green players can choose which picture will be shown to the red player, for the other green player this is determined randomly.

The red player then assigns the task to invest to you or the other green player.

The designated green player can invest or refuse to invest. The other green player has no decision to make.

The designated green player earns €2.00 if he or she accepts to invest, and €2.20 if he or she refuses to invest. The red player earns €2.00 if the designated green player accepts to invest, and €1.00 if the designated green player refuses to invest. The other green player always earns €1.00.

There will be 12 rounds, you will be paid for all rounds.

You will be paired with different players in each round. You will never be matched twice with the same red player throughout the entire experiment.

Summary [undesirable task treatment]

One of the green players can choose which picture will be shown to the red player, for the other green player this is determined randomly.

The red player then assigns the task to invest to you or the other green player.

The designated green player can invest or refuse to invest. When the designated green player refuses, the other green player has to invest.

The (green) player that invests earns €1.00. The other (red and green) players earn €2.00 each if the designated player accepts to invest, and €1.20 each if the designated player refuses to invest.

There will be 12 rounds, you will be paid for all rounds.

You will be paired with different players in each round. You will never be matched twice with the same red player throughout the entire experiment.

Quiz questions [identical for both treatments]

Please answer the following quiz questions. If you have any questions please press the call button on the wall next to you.

In each of the 12 rounds, you will be matched:

- with the same players
- with different players

Suppose you are chosen to invest by the red player. You refuse to invest. How much will the red player, you, and the other green player earn?

- The red player would earn: _____ euro
- You would earn: _____euro
- The other green player would earn: _____ euro

Suppose you are chosen to invest by the red player. You invest. How much will the red player, you, and the other green player earn?

- The red player would earn: _____ euro
- You would earn: _____euro
- The other green player would earn: _____ euro

Suppose the other green player is chosen to invest by the red player. The other green player invests. How much will the red player, you, and the other green player earn?

- The red player would earn: _____ euro
- You would earn: _____euro
- The other green player would earn: _____ euro

Suppose the other green player is chosen to invest by the red player. The other green player refuses to invest. How much will the red player, you, and the other green player earn?

- The red player would earn: _____ euro
- You would earn: _____euro
- The other green player would earn: _____ euro

C.2 Experiment II

C.2.1 Instructions for red players (managers)

General information [identical for both treatments]

Thank you for participating in this study. Please read the instructions carefully and make sure that your mobile phone is turned off. You can earn money depending on your own choices and the choices of other participants.

Today's experiment consists of several independent parts. This is the first part. At the beginning of each part you will receive new instructions. Your decisions in one part do not influence the proceedings or earnings of any other part.

In this experiment, there are two types of players: red and green. The green players are all students from another town (Amsterdam). The red players are students from Tilburg. You are one of the red players.

Investment decision [desirable task treatment]

In every round, you are paired with two green players (green A and green B). Exactly one of the green players can make an investment.

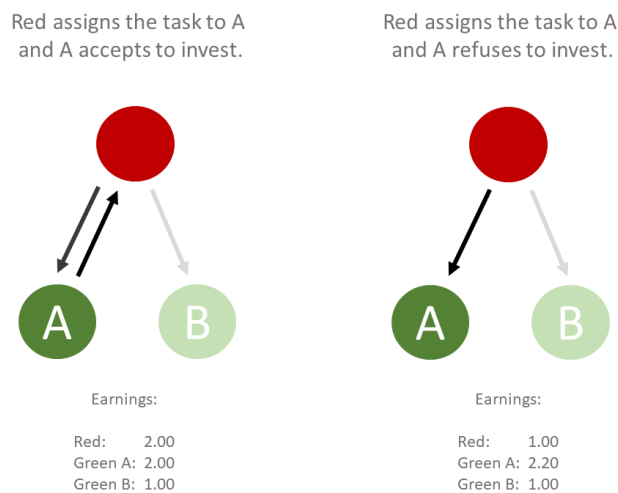

Your task is to assign the investment task to one of the green players. That green player becomes the "designated" player. The designated green player can accept or refuse to invest. The other green player has no decision to make.

The earnings are as follows:

You earn €2.00 if the designated green player accepts to invest, and €1.00 if the designated green player refuses to invest. The designated green player earns €2.00 if he or she accepts to invest, and €2.20 if he or she refuses to invest. The other green player always earns €1.00.

Suppose, for instance, that you assign the investment task to green A. If green A accepts to invest, green A and you earn €2.00 each, and green B earns €1.00. If green A refuses to invest, green A earns €2.20, and green B and you earn €1.00 each.

The picture below summarizes the possible earnings when you assign the investment task to green A. Of course, this is just an example; you could also assign the investment task to green B, and the earnings of A and B are then reversed.

Investment decision [undesirable task treatment]

In every round, you are paired with two green players (green A and green B). Exactly

one of the green players has to make an investment.

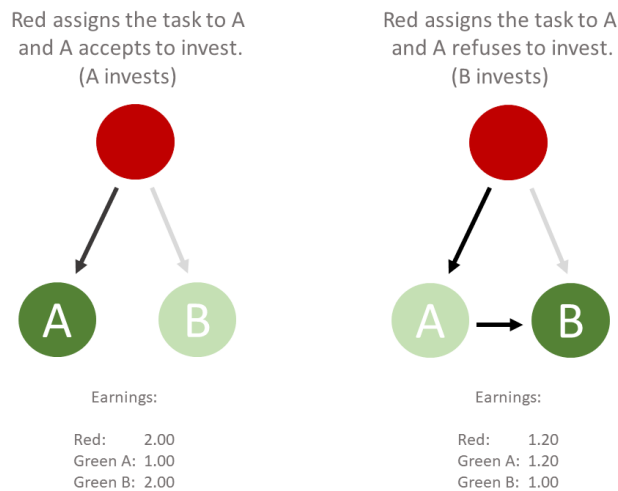

Your task is to assign the investment task to one of the green players. That green player becomes the "designated" player. The designated green player can accept or refuse to invest. If the designated green player refuses, the other green player has to invest.

The earnings are as follows:

The green player that ends up making the investment always earns €1.00. The other green player and you earn €2.00 each if the designated green player accepts to invest, and €1.20 if the designated green player refuses to invest.

Suppose, for instance, that you assign the investment task to green A. If green A accepts to invest, he or she earns €1.00, and you and green B earn €2.00 each. If green A refuses to invest, then green B has to invest. Green A and you earn €1.20 each, and green B earns €1.00.

The picture below summarizes the possible earnings when you assign the investment task to green A. Of course, this is just an example; you could also assign the investment task to green B, and the earnings of A and B are then reversed.

Pictures and rounds [identical for both treatments]

In total, there will be 6 rounds in this part. You will be paid for every round.

When you assign the task to invest, you will see pictures of the green players. The green players make new pictures at the beginning of every round.

In every round, you will learn whether the green player you assigned the task to accepted or refused to invest.

In half of the rounds, you will be inactive and do not have to make a decision. You will receive €1.00 for each round that you are inactive.

You will be paired with different players in each round. You will never be matched twice with the same green player throughout the entire experiment.

Summary [desirable task treatment]

If you are active in a round, you will see the pictures of the green players you are

paired with.

You assign the task to invest to one of the green players.

The designated green player can invest or refuse to invest. The other green player has no decision to make.

You earn €2.00 if the designated green player accepts to invest, and €1.00 if the designated green player refuses to invest. The designated green player earns €2.00 if he or she accepts to invest, and €2.20 if he or she refuses to invest. The other green player always earns €1.00.

There will be 6 rounds in this part, you will be paid for all rounds.

You will be paired with different players in each round. You will never be matched twice with the same green player throughout the entire experiment.

In half of the rounds you will be inactive. If you are inactive you will receive €1.00

Summary [undesirable task treatment]

If you are active in a round, you will see the pictures of the green players you are paired with.

You assign the task to invest to one of the green players.

The designated green player can invest or refuse to invest. When the designated green player refuses, the other green player has to invest.

The (green) player that invests earns €1.00. The other (red and green) players earn

€2.00 each if the designated player accepted to invest, and €1.20 each if the designated player refused to invest.

There will be 6 rounds in this part, you will be paid for all rounds.

You will be paired with different players in each round. You will never be matched twice with the same green player throughout the entire experiment.

In half of the rounds you will be inactive. If you are inactive you will receive €1.00

Quiz questions [identical for both treatments]

Please answer the following quiz questions. If you have any questions please raise your hand.

In each of the 6 rounds, you will be matched:

- with the same players
- with different players

Suppose the green player you assigned the task to refuses to invest. How much will you, the designated green player, and the other green player earn?

- You would earn: ____euro
- The designated green player would earn: ____ euro
- The other green player would earn: ____ euro

Suppose the green player you assigned the task to invests. How much will you, the designated green player, and the other green player earn?

- You would earn: _____euro
- The designated green player would earn: _____ euro
- The other green player would earn: _____ euro

C.2.2 Instructions for green players (workers)

Welcome [identical for both treatments]

Thank you for participating in this study. Please read the instructions carefully and make sure that your mobile phone is turned off. You can earn more money depending on your own choices and the choices of other participants.

In this experiment, you will be asked to take pictures of yourself. This is what we will do with your pictures:

Suppose you are chosen to invest by the red player. You invest. How much will the red player, you, and the other green player earn?

- The red player would earn: _____ euro
- You would earn: _____euro
- The other green player would earn: _____ euro

Suppose the other green player is chosen to invest by the red player. The other green player invests. How much will the red player, you, and the other green player earn?

- The red player would earn: _____ euro
- You would earn: _____euro
- The other green player would earn: _____ euro

Suppose the other green player is chosen to invest by the red player. The other green player refuses to invest. How much will the red player, you, and the other green player earn?

- The red player would earn: _____ euro
- You would earn: _____euro
- The other green player would earn: _____ euro

Taking pictures [identical for both treatments, shown again at the beginning of every round]

In the next steps, you will take a picture of yourself. To ensure that the pictures are useable, please pay attention to the following factors:

1. Look straight into the camera,
2. Capture your entire face on the picture,
3. Do not wear glasses or other items that cover your face.
4. Do not show your hands on the picture.
5. If you have long hair, please hold them back with an elastic band so that they do not fall into your face.

Take a picture for the next round [identical for both treatments, shown again at the beginning of every round]

In total, you have 3 tries to make your picture. This is your first try.

When you take a picture, there will be a 3-seconds countdown.

Picture result [identical for both treatments, shown again at the beginning of every round]

Below is the picture that you took. Please indicate whether you are satisfied with it or want to retake the picture.

C.3 Survey measures

C.3.1 Strategic Reasoning

Instructions

You will now play the following game with the computer. Imagine there are 15 chips on the table. You and the computer take turns. Every time it is a player's turn, that player can remove 1, 2, or 3 chips from the table. The player who takes the final chip wins the game. You will be the player that starts.

Instructions

You will play another game with the computer. This time there are 17 chips on the table. You and the computer again take turns. Every time it is a player's turn, that player can remove 1, 2, 3, or 4 chips from the table. The player who takes the final chip wins the game. You will be the player that starts.

C.3.2 Angry button test

Decision

Below you see pictures of participants in another experiment. They played following game:

In the game, there were two types of players: 'proposers' and 'responders'. Each proposer could make an offer on how to divide €9. The proposer could choose

between two options:

Option A gives €4 to the proposer and €5 to the responder,

Option B gives €7 to the proposer and €2 to the responder.

If the responder accepts the offer, the money was divided as proposed. If the responder rejects the offer, none of them earned money.

All the people on the pictures below were responders in this game. All of them were offered Option B (€7 for the proposer and €2 for the responder). 5 of the responders rejected the offer, the others accepted the offer. **Please select the 5 people who you think rejected the offer.**

C.3.3 Reading the mind in the eyes test

Instructions

For each set of eyes, choose and select which word best describes what the person in the picture is thinking or feeling. You may feel that more than one word is applicable but please choose just one word, the word which you consider to be most suitable. Before making your choice, make sure that you have read all 4 words. You should try to do the task as quickly as possible but you will not be timed. If you really don't know what a word means you can look it up by moving your mouse over the question mark. By doing so, you will also see the Dutch translation.

Below is an example. You can proceed by selecting a word and clicking on 'OK'.

Appendix D Proofs

Proof of Lemma 1. Fix an equilibrium strategy in which t_1 sends message m_1 and $t_2 > t_1$ sends message m_2 . Let $r_1 = r(m_1)$ and $r_2 = r(m_2)$. The incentive compatibility constraints imply that:

$$\theta r_1 - k(m_1 - t_1)^2 \geq \theta r_2 - k(m_2 - t_1)^2, \quad (4)$$

and

$$\theta r_2 - k(m_2 - t_2)^2 \geq \theta r_1 - k(m_1 - t_2)^2. \quad (5)$$

The two constraints together imply that:

$$2(t_2 - t_1)(m_2 - m_1) \geq 0. \quad (6)$$

This implies that for any $t_2 > t_1$, $m_2 \geq m_1$.

Proof of Proposition 1. We first show that full separation is not possible. If $\theta > 0$, the solution to equation (3) is given by (see [Kartik \(2009\)](#)):

$$e^{-\frac{2k}{\theta}\rho(t)} = 1 - \frac{2k}{\theta}(\rho(t) - t). \quad (7)$$

Together with the boundary condition that $\rho(0) = 0$, this implies that the highest type that can separate is given by $t^h = 1 - \frac{\theta}{2k}(1 - e^{-\frac{2k}{\theta}}) < 1$. If $\theta < 0$, the solution to

equation (3) is given by:

$$e^{-\frac{\theta}{2k}(\rho(t)-1)} = 1 - \frac{2k}{\theta}(\rho(t) - t). \quad (8)$$

Together with the boundary condition that $\rho(1) = 1$, this implies that the lowest type that can separate is given by $t^l = \frac{2k}{\theta}(1 - e^{\frac{2k}{\theta}}) > 0$.

We next show that there can be at most be a single pool. We do this for the case $\theta > 0$ (the case with $\theta < 0$ is symmetric). Consider an equilibrium that contains an interval (t_1, t_2) on which all types pool on some message $m_1 < 1$, and let $t_2 < 1$. We invoke the equilibrium refinement D1 to show that there is a profitable deviation for some type $\hat{t} = t_2 - \varepsilon$ for $\varepsilon \rightarrow 0$. Consider a deviation to message $\hat{m} = m_1 + \varepsilon$ and a receiver's response \hat{r} that makes type \hat{t} indifferent between sending message \hat{m} and his equilibrium message m_1 (resulting in $r_1 = r(m_1)$):

$$r_1\theta - k(m_1 - \hat{t})^2 = \hat{r}\theta - k(\hat{m} - \hat{t})^2. \quad (9)$$

It is straightforward to show that for this action by the receiver, the difference in payoffs between sending \hat{m} and sending m_1 for any type $\tilde{t} \in (t_1, \hat{t})$ is given by:

$$\Delta = -k(\hat{t} - \tilde{t})(\hat{m} - m_1) < 0. \quad (10)$$

Then, by monotonicity and D1, the receiver should not put any positive beliefs on

the out-of-equilibrium action coming from type \tilde{t} . It is also straightforward to show that the same is true for any $\tilde{t} < t_1$. But then $\hat{r} > r(m_1)$ (strict, because there is a interval of types sending m_1). This means that there is some type \hat{t} that can strictly increase the likelihood of getting the task by an arbitrarily small change in lying cost, a strictly profitable deviation.

The above implies that all pooling must occur at $m = 1$, implying $\rho(t) > t$ for all types $t < 1$ that send message $m = 1$. That $\rho(t) > t$ on an interval in which types separate is immediate from equation (3). Similarly, for $\theta < 0$, all pooling must occur at $m = 0$, implying $\rho(t) < t$ for all types $t > 0$ that send message $m = 0$. That $\rho(t) < t$ on an interval in which types separate is again immediate from equation (3).
